MORPHOLOGICAL, TEMPORAL, AND NODAL ACCUMULATION OF NUTRIENTS BY DETERMINATE SOYBEAN

E. J. Sadler, D. L. Karlen, R. E. Sojka, and H. D. Scott[1]

Coastal Plains Soil and Water Conservation Research Center, USDA-ARS, P.O. Box 3039, Florence, SC 29501

ABSTRACT: Crop growth models that account for nutrient accumulation offer insight into soil fertility and plant nutrition interactions. This understanding provides opportunities to develop improved management practices. During the 1980s, several process-level growth models were developed for soybean [*Glycine max* (L.) Merr.]. Model validation and application to different locations and weather require detailed, independent data sets. An extensive data set describing the nutrient status of a determinate soybean ('Bragg') was collected in 1979 on a Goldsboro (Aquic Paleudult) loamy sand near Florence, SC, USA. Because of its importance to subsequent model development, we concluded that providing this entire data set in a readily accessible form was a logical step in the course of this experiment. We report here, in tabular form, mean and standard deviation data for aerial accumulation of dry matter and eight nutrients (N, P, K, Ca, Mg, Mn, Fe, and Zn) for 10 dates, for four plant components (stems, leaves, petioles, pods, and total), and for each node (and whole plant). We will provide, upon arrangement, these same data on diskette for use in simulation models or other applications.

INTRODUCTION

Model development is an iterative procedure by which mathematical equations of a model are gradually improved as a result of evaluations with increasing numbers of data sets. For soybean growth and development, this has resulted in the process-level models such as SOYGRO[2], for example. However, there remains a critical need for independent data to validate the models for environments and cultivars other than those used for model development.

Historically, most nutrient data has been published as concentrations because they can be used to diagnose nutrient deficiencies using either critical values[3] or Diagnosis Recommendation Integrated System [DRIS][4]. However, validating plant growth models requires nutrient and dry matter accumulation data. Fertilizer recommendations are more easily recognized from nutrient accumulation expressed in mass per unit area rather than from concentration. Furthermore, nutrient accumulation curves can be differentiated over time to produce nutrient accumulation rates. Illustrations of this type of analysis exist for corn[5,6] and for wheat[7].

Aerial dry matter and nutrient concentrations for an intensive experiment with determinate soybean have been documented graphically in this journal[8,9,10,11] as functions of time, plant part, and nodal position. Recognizing both the unique combination of temporal and nodal information represented therein and the modelers' need for independent data, we concluded that providing the entire data set in a readily accessible form was a logical step in the course of communicating the results of the experiment. While preparing this information on determinate soybean, we became aware of a data set[12] describing row spacing and soil water effects on indeterminate soybean grown in Iowa, and coincidentally, in the same year. For two sampling dates in their study, values for leaf area, pod number, and component masses were published as a function of height, but this was not done for nutrient information. To our knowledge, the information presented here on determinate soybean is the only

data set with nutrient accumulation as a function of plant part, time, and nodal position

MATERIALS AND METHODS

Crop culture, weather, sampling methods, soil analyses, and nutrient analysis procedures have been reported previously[8,9,10,11]. Nutrient concentrations and aerial dry matter data that were used for graphs in those publications were used to produce the nutrient accumulation tables reported here. Nutrient concentrations were multiplied by aerial dry matter values for each day, node, and plant part, and then converted to kg/ha. Tables for each nutrient were created using PROC TABULATE of SAS[13,14], including mean and standard deviation of the individual cells, and summary values across plant part and node. These statistics represent the mean and standard deviation of the nutrient accumulation; that is, individual measurements of dry mass and concentration multiplied, rather than means of each multiplied. This procedure accounted for the cross correlation between mass and concentration. The original sampling had 4 replicates at each of 4 locations per treatment. For this analysis, locations were considered a second hierarchy of replicate, resulting in 16 points per mean value. There were 8226 dry matter samples. For about 2500 samples, there was not enough plant material to perform the concentration analysis, so replicates were physically combined. Samples were also combined over replicates for the last 4 dates in order to reduce the total number from about 4000 to about 1000. For all pooled cases, the separate masses were recorded, then the physical samples combined across replications as needed to provide a suitable sample. In about 600 cases, replicates 1 and 2 or 3 and 4 were pooled; where samples were smaller still (about 1000 cases), all 4 replicates were pooled; where samples were smallest, the pooling extended to locations as well (45 determinations were made on the combined material from all 16 dry matter samples). In order to produce the best estimate of data variance, individual masses were multiplied by the concentration that was common to the combined sample. The standard deviation

was then indicative of variation in the mass alone. This was done by necessity only. It is expected that concentration was by far more conservative than mass, thus the variation in mass for pooled samples represents most of the variation in the accumulation of a nutrient.

RESULTS AND DISCUSSION

Temporal and nodal changes in soybean growth, development, and nutrient concentration from this experiment were discussed previously[8,9,10,11], but are summarized to provide insight to analyses of these data available in the literature. Scott et al.[8] presented growth analysis and statistical representations of partitioning coefficients and of sample variability. Sojka et al.[9] showed that nodal and temporal mean K and Ca concentrations varied over time and node, but mean Mg concentrations did not. They also concluded that mean concentrations of these elements in all plant parts can vary two fold or more depending on plant age and node. Sojka et al.[10,11] described variation in N, P, Fe, Mn, and Zn that was similar to variation in K and Ca. These presentations were normally 2-dimensional response surfaces describing concentration, sample variability, or other characteristics over time and node. These graphs are easily interpreted for trends and main effects, but are not easily used for model validation.

The tabular presentation of accumulation data from this experiment in Tables 1 through 9, presented as an appendix, allows potential users to scrutinize accumulation and partitioning of aerial dry matter and eight essential plant nutrients. We will provide this information and daily weather data on diskette upon request. Each nutrient is given in a separate table, with the four plant parts and total comprising the headings of the columns. Time is the major vertical dimension, and nodal position the minor, resulting in 171 observations over date and node. After each date, the sum of accumulated nutrient over the nodes is given. Each cell in the table holds the mean and standard deviation of the value.

TABLE 1. Aerial dry matter accumulation means and standard deviations for each day after planting (DAP), node, and plant part. Values are in kg/ha, and planting date was 143 (23 May).

SUMMARY

Independent validation of process-based simulation models requires extensive data sets that are often very costly to obtain. This paper provides an extensive dry matter and nutrient accumulation data set (also available in machine format) for a maturity Group VII, determinate soybean ('Bragg') grown on a Goldsboro loamy sand in the South Carolina Coastal Plain.
